ÍNDICE

1. Serie unimodal de números

1.1 Algoritmo Evidente
1.2 Primera solución DyV
1.3 Segunda solución DyV
1.4 Comparación entre algoritmos

2. Comparación de preferencias

2.1 Algoritmo Evidente
2.2 Solución DyV
2.3 Comparación entre algoritmos

3. Bibliografía

En lo que sigue, los miembros del grupo combinamos sistemas operativos y maquinas diferentes para experimentar de la forma más completa y variada la eficiencia de los algoritmos. Estas son las prestaciones de las máquinas:

- Luis: Fujitsu. Intel Core i5. Ubuntu 14.04
- Ignacio: Toshiba. Intel Core i7. Ubuntu 14.04
- Diego: Mac. Intel Core i7. OS X El Capitán
- Miguel Ángel: Toshiba. Intel Core i7. Windows 10

1. Serie unimodal de números

Nuestro problema consistía en que se nos daba un vector de números que crecía estrictamente hasta un determinado índice a partir del cual decrecía de manera estricta. Debemos devolver mediante nuestros algoritmos el índice en el que dicho cambio de crecimiento se produce.

1.1 Algoritmo Evidente

En este primer algoritmo que hemos implementado para la resolución de nuestro problema hemos utilizado una versión muy simple que recorre el vector de manera secuencial. Nuestra intención es ir recorriéndolo desde la posición 0 hasta el final. Si nos encontramos un punto en el que el vector en vez de crecer decrece no continuamos avanzando ya que hemos llegado al punto que andábamos buscando, es decir, si v[i]>v[i+1] siendo el índice i el primero con el que ocurre esto.

Presentamos el código:

```
#include <iostream>
#include <vector>
#include <cstdlib>
#include <cstdio>
#include <ctime>
#include <climits>
#include <cassert>
#include <chrono>

using namespace std;

double uniforme()
{
double u;
  u = (double) rand();
  u = u/(double)(RAND_MAX+1.0);
 return u;
}

int serie_unimodal_secuencial(int *v, int n)
{
        int i=0;
        int maximo=0;
        while(v[i]<v[i+1] && ((i+1)<n))
                i++;
```

```
        //maximo=v[i];
        return i;
}

using namespace std::chrono;

int main(int argc, char * argv[])
{
  high_resolution_clock::time_point t1, t2;
  if (argc != 2)
    {
      cerr << "Formato " << argv[0] << " <num_elem>" << endl;
      return -1;
    }

  int n = atoi(argv[1]);

  int * T = new int[n];
  assert(T);

srand(time(0));
double u=uniforme();
int p=1+(int)((n-2)*u);
T[p]=n-1;
for (int i=0; i<p; i++) T[i]=i;
for (int i=p+1; i<n; i++) T[i]=n-1-i+p;

  t1=high_resolution_clock::now();
  int pos_maximo_secuencial=serie_unimodal_secuencial(T,n);
  t2=high_resolution_clock::now();
  duration<double> transcurrido = duration_cast<duration<double> >(t2-t1);
  cout << n << " " << transcurrido.count() << "\n";

  return 0;
}
```

Vemos que la eficiencia del algoritmo en este caso es lineal comparando entre sí la suma al cuadrado de los residuos de los distintos ajustes realizados.
Lineal = 9.07552e-06
nlogarítmica = 9.73699e-06
logarítmica = 7.55603e-05

1.2 Primera Solución DyV

En esta primera solución en la que empleamos DyV. Comenzamos presentando el código:

```
#include <iostream>
#include <vector>
#include <cstdlib>
#include <cstdio>
#include <ctime>
#include <climits>
#include <cassert>
#include <chrono>

using namespace std;
```

```
int& buscaPuntoDeCambio(int* v, int indice1, int indice2, int& res)
{
  int indi=(indice1+indice2)/2;
  if(v[indice1]>v[indice1+1])
  {
    res=indice1;
    return res;
  }
  else if(v[indice2]>v[indice2-1])
  {
    res=indice2;
    return res;
  }
  else if(v[indi]-v[indi-1]>0 &&  v[indi]-v[indi+1]>0)
  {
    res=indi;
    return res;
  }
  else
  {
    buscaPuntoDeCambio(v, indice1, indi, res);
    buscaPuntoDeCambio(v, indi, indice2, res);
  }

}

double uniforme()
{
double u;
  u = (double) rand();
  u = u/(double)(RAND_MAX+1.0);
 return u;
}

using namespace std::chrono;

int main(int argc, char* argv[])
{
  high_resolution_clock::time_point t1, t2;
  if(argc<2)
  {
    cout << "Falta el numero de componentes.\n";
    exit(1);
  }
  int n = atoi(argv[1]);

  int * T = new int[n];
  assert(T);

  srand(time(0));
  double u=uniforme();
```

```
  int p=1+(int)((n-2)*u);
  T[p]=n-1;
  for (int i=0; i<p; i++) T[i]=i;
  for (int i=p+1; i<n; i++) T[i]=n-1-i+p;

  int res=0;
  t1=high_resolution_clock::now();
  buscaPuntoDeCambio(T,0,n-1, res);
  t2=high_resolution_clock::now();
  int punto_cambio=res;
  duration<double> transcurrido = duration_cast<duration<double> >(t2-t1);
  cout << n << " " << transcurrido.count() << "\n";

  return 0;
}
```

En esta implementación el método que seguimos para obtener el punto de cambio es:
1) Obtenemos el punto medio del vector.
2) Comprobamos si los extremos son el punto que andamos buscando. Si el extremo izquierdo fuera este punto entonces el vector decrecería a partir de dicho punto. Si el extremo derecho fuera el punto entonces el vector crecería hasta dicho extremo.
3) Comprobamos si el punto de cambio es el propio punto medio mediante la comprobación del elemento que antecede al punto medio y el elemento que precede al mismo.
4) Si ninguna de estas comprobaciones nos otorga el punto entonces llamamos recursivamente al algoritmo para una sola de las partes del vector. Si a la derecha del punto medio el vector sigue creciendo descartamos la parte izquierda, si a la izquierda del punto medio el vector decrece descartamos la parte derecha.

Vemos que la eficiencia de dicho algoritmo es logarítmica, lo cual es confirmado al ajustar la función a los datos obtenidos. Lo observamos en este caso con la suma al cuadrado de los residuos obtenida en los ajustes.
Lineal = 2.85144e-10
nlogarítmica = 3.7745e-10
logarítmica = 2.42327e-10

Datos:

1.3 Segunda Solución DyV

En esta segunda solución que planteamos para nuestro problema comenzaremos como en la anterior, presentando el código:

```
#include <iostream>
using namespace std;
#include <ctime>
#include <cstdlib>
#include <climits>
#include <cassert>
//#include <mach/mach_time.h>
#include <cstdio>
#include <chrono>

int &  rift_lims(int* arr, int beg, int end, int & res){

  int N = end - beg;

  if (N  == 1) {
    res = beg;
    return arr[beg];
  }
  else if (arr [beg + N/2 - 1] < arr [end - 1])
    return rift_lims(arr, beg + N/2 , end, res);
  else
    return rift_lims(arr,beg, beg + N/2, res);
}
```

```
int rift(int * arr, int n, int & res){

  int beg = 0, end = n;

  return rift_lims(arr,beg,end,res);
}

double uniforme()
{
double u;
  u = (double) rand();
  u = u/(double)(RAND_MAX+1.0);
 return u;
}

int main(int argc, char * argv[])
{

  if (argc != 2)
    {
      cerr << "Formato " << argv[0] << " <num_elem>" << endl;
      return -1;
    }

  int n = atoi(argv[1]);

  int * T = new int[n];
  assert(T);

  srand(time(0));
  double u=uniforme();
  int p=1+(int)((n-2)*u);
  T[p]=n-1;
  for (int i=0; i<p; i++) T[i]=i;
  for (int i=p+1; i<n; i++) T[i]=n-1-i+p;

#ifdef _PRINT_IT_
  cout << "El vector generado es:" << endl;
  for (int j=0; j<n; j++) {cout << T[j] << " ";}
  cout << endl;
#endif

int res=0;
std::chrono::high_resolution_clock::time_point t1, t2;

t1=std::chrono::high_resolution_clock::now();
rift(T,n,res);
t2=std::chrono::high_resolution_clock::now();
int punto_cambio=res;

std::chrono::duration<double>                                    transcurrido                                    =
std::chrono::duration_cast<std::chrono::duration<double> >(t2-t1);
```

```
cout << n << " " << transcurrido.count() << "\n";

#ifdef _PRINT_IT_
cout << endl << "La posicion en la que cambia la monotonia es: " << punto_cambio << endl ;
#endif
}
```

El algoritmo utilizado en esta segunda solución es el siguiente:
1) Aprovechando la estructura con la que se genera el vector aleatorio tomamos inicialmente el punto medio y el extremo derecho del vector. Si el valor almacenado en el punto medio es mayor que el almacenado en el punto extremo tomamos la parte izquierda del vector. Si el valor almacenado en el punto medio es menor que el del extremo tomaremos la parte derecha del vector.
2) Repetiremos esto hasta llegar al caso en que el tamaño del vector sea 1 y por tanto el punto sea el único que nos queda.

La eficiencia de este algoritmo es logarítmica como se observa en la suma al cuadrado de los residuos que nos arroja el ajuste de las funciones mediante gnuplot:
nlogarítmica = 1.0888e-10
logarítmica = 6.58058e-11

Pasamos a exponer los datos y gráficas obtenidas:

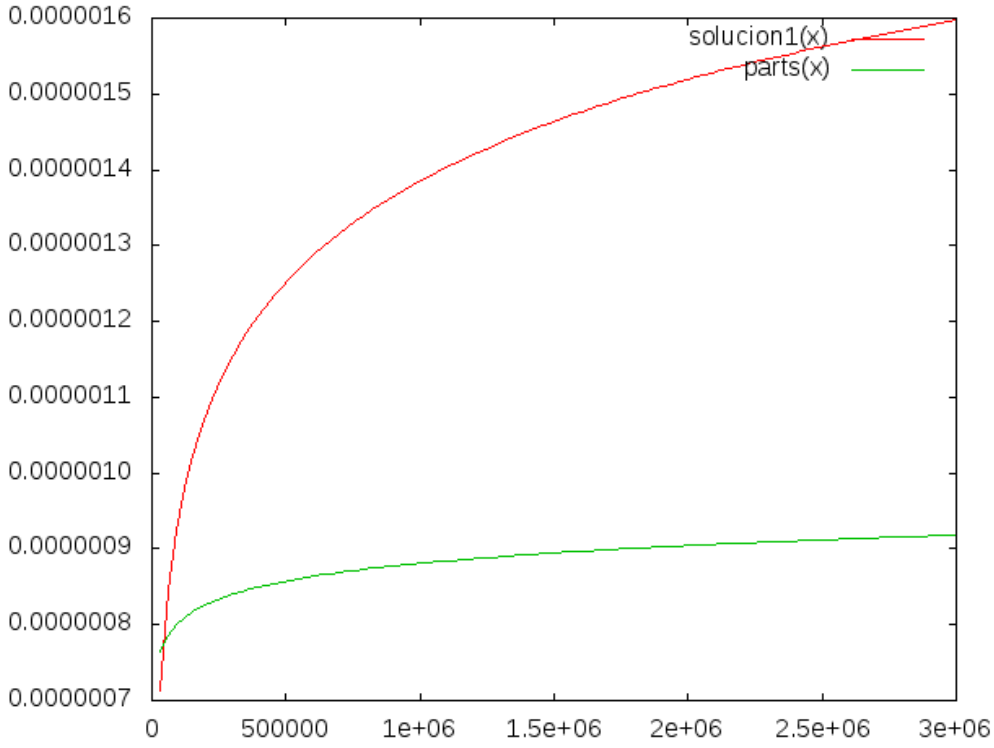
1.4 Comparación entre algoritmos

Para la comparación nos valdremos de la función logarítmica que hemos ajustado para la primera y la segunda solución DyV planteadas en la resolución del problema.



Como se puede observar en la gráfica la primera opción propuesta es menos eficiente que la segunda ya que la función ajustada y evaluada en el mismo rango de puntos perteneciente al primer algoritmo crece más rápido que la función ajustada para el segundo algoritmo.

2. Comparación de preferencias

El problema en este caso consiste en contar el número de inversiones que se producen en un vector considerándose como inversión que v[i]>v[j] con i<j.

2.1 Algoritmo Evidente

Comenzamos presentando el código del algoritmo:

```
#include <iostream>
using namespace std;
#include <ctime>
#include <cstdlib>
#include <climits>
#include <cassert>
#include <chrono>

double uniforme()
{
 int t = rand();
 double f = ((double)RAND_MAX+1.0);
 return (double)t/f;
}

int CuentaIntercambios(int* v, int tam)
{
  int inter=0;
  for(int i=0;i<tam;i++)
  {
    for(int j = i; j < tam;j++)
    {
      if(v[j]<v[i])
      {
        inter++;
      }
    }
  }
  return inter;
}

using namespace std::chrono;

int main(int argc, char * argv[])
{
```

```
 high_resolution_clock::time_point t1, t2;

 if (argc != 2)
  {
   cerr << "Formato " << argv[0] << " <num_elem>" << endl;
   return -1;
  }

 int n = atoi(argv[1]);

 int * T = new int[n];
 assert(T);

 srand(time(0));

 for (int j=0; j<n; j++) T[j]=j;
 for (int j=n-1; j>0; j--) {
   double u=uniforme();
   int k=(int)(j*u);
   int tmp=T[j];
   T[j]=T[k];
   T[k]=tmp;
 }
 for (int j=0; j<n; j++) {cout << T[j] << " ";}
 cout << endl;

 t1=high_resolution_clock::now();
 int valor = CuentaIntercambios(T,n);
 t2=high_resolution_clock::now();
 duration<double> transcurrido = duration_cast<duration<double> >(t2-t1);
 cout << "El número de inversiones es: " << valor << endl;
 cout << n << " " << transcurrido.count() << endl;

}
```

El algoritmo consiste en recorrer para cada uno de los índices el resto del vector comprobando si se produce la condición de inversión definida en el enunciado del ejercicio.

La eficiencia de este algoritmo como se puede observar en la suma al cuadrado de los residuos es cuadrática.

Cuadrática = 0.00112279
Logarítmica = 2.11738
nlogarítmica = 0.39753
Lineal = 0.239461

Presentamos aquí las tablas y gráficas:

2.2 Solución DyV

Para la solución propuesta en el ejercicio siguiendo el patrón DyV hemos usado el código que teníamos de la primera práctica correspondiente al mergesort. Comenzamos presentando el código:

```
#include <iostream>
using namespace std;
#include <ctime>
#include <cstdlib>
#include <climits>
#include <cassert>
#include <chrono>

int contador=0;

double uniforme()
{
 int t = rand();
 double f = ((double)RAND_MAX+1.0);
 return (double)t/f;
}

inline static void CuentaIntercambiosDYV(int T[], int num_elem);

static void mergesort_lims(int T[], int inicial, int fin);

static void fusion(int T[], int inicial, int fin, int U[], int V[]);

void CuentaIntercambiosDYV(int T[], int num_elem)
{
  contador=0;
  mergesort_lims(T, 0, num_elem);
}

static void mergesort_lims(int T[], int inicial, int fin)
{
    int k = (fin - inicial)/2;

    int * U = new int [k - inicial +1];
    assert(U);
    int l, l2;
    for (l = 0, l2 = inicial; l < k; l++, l2++)
                U[l] = T[l2];
    U[l] = INT_MAX;

    int * V = new int [fin - k+1];
    assert(V);
    for (l = 0, l2 = k; l < fin - k; l++, l2++)
                V[l] = T[l2];
    V[l] = INT_MAX;
```

```
    if(k!=0)
    {
     mergesort_lims(U, 0, k);
    }
    if(fin>1)
     mergesort_lims(V, 0, fin - k);
    fusion(T, inicial, fin, U, V);
    delete [] U;
    delete [] V;
}

static void fusion(int T[], int inicial, int fin, int U[], int V[])
{
  int j = 0;
  int k = 0;
  for (int i = inicial; i < fin; i++)
    {
      if (U[j] <= V[k]) {
          T[i] = U[j];
          j++;
      }
      else{
                  T[i] = V[k];
          k++;
            contador+=((fin - inicial)/2 -inicial-j);

      };
    };
}

using namespace std::chrono;

int main(int argc, char * argv[])
{
  high_resolution_clock::time_point t1, t2;

  if (argc != 2)
    {
      cerr << "Formato " << argv[0] << " <num_elem>" << endl;
      return -1;
    }

  int n = atoi(argv[1]);

  int * T = new int[n];
  assert(T);

  srand(time(0));

  for (int j=0; j<n; j++) T[j]=j;
  for (int j=n-1; j>0; j--) {
```

```
    double u=uniforme();
    int k=(int)(j*u);
    int tmp=T[j];
    T[j]=T[k];
    T[k]=tmp;
  }

  int res2=CuentaIntercambios(T,n);
  t1=high_resolution_clock::now();
  CuentaIntercambiosDYV(T,n);
  t2=high_resolution_clock::now();
  duration<double> transcurrido = duration_cast<duration<double> >(t2-t1);
  cout << n << " " << transcurrido.count() << endl;

}
```

Este algoritmo sigue el patrón de división de vectores utilizado en mergesort. Cuando se producen las comprobaciones en la función de fusión utilizamos el else (el cual nos asegura las condiciones del problema) para aumentar el contador k-inicial-j veces contando con ello todos los intercambios correspondientes.

La eficiencia del algoritmo como se puede observar mediante la suma al cuadrado de los residuos es nlogarítmica:
Logarítmica = 0.908574
nlogarítmica = 0.00384006

Presentamos aquí las gráficas y las tablas de datos:

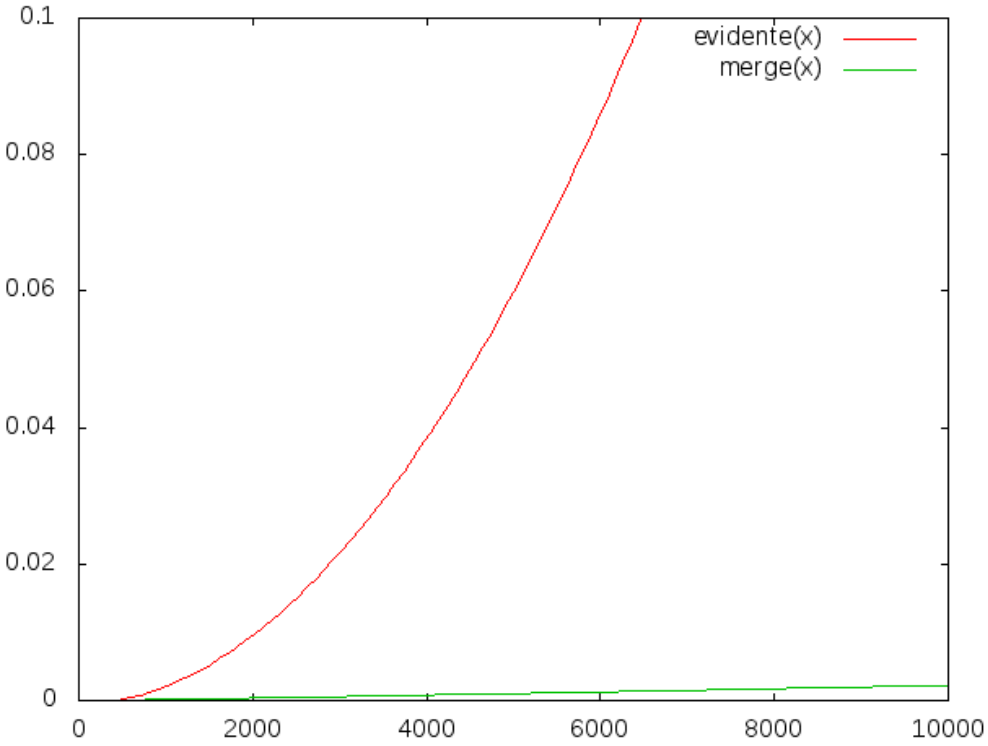
2.3 Comparación entre algoritmos



Como observamos en la gráfica con las funciones que ajustan a cada uno de los algoritmos el algoritmo de mergesort modificado es mucho mas eficiente que el evidente. Esto se produce porque la eficiencia del algoritmo evidente es cuadrática mientras que la del algoritmo modificado de mergesort es nlogarítmica.
